

Riya was an aspiring data scientist from Jaipur who loved solving real-world problems using technology. She spent her days learning Python, machine learning, and data visualization techniques.

One day, she came across the idea of building a PDF summarizer. Curious and excited, she began exploring how text could be extracted from documents using tools like PyMuPDF. At first, the extracted text looked messy, but she quickly learned that breaking the text into smaller chunks made it easier to process.

Riya then discovered embeddings, which convert text into numerical vectors. These vectors helped her store information efficiently and retrieve relevant parts when users asked questions. She used FAISS to build a simple yet powerful search system.

After integrating a language model, her application could now summarize documents and answer questions accurately. Riya realized that building AI systems was not just about using models, but about connecting multiple components together.

Her project became a success, and she gained confidence to build more advanced applications in the future.
